Abstract

SnO₂ nanobelts functionalized with Au were prepared using a three-step process consisting of the thermal evaporation of Sn powders, sputter deposition of Au, and annealing. Multiple-networked sensors were fabricated using Au-functionalized SnO₂ nanobelts. Scanning electron microscopy revealed nanobelts with widths ranging from a few hundred nanometers to a few micrometers, thicknesses of a few hundred nanometers, and lengths ranging from a few to a few tens of micrometers coated with the Au nanoparticles with a mean diameter of ~200 nm. The bare SnO₂ nanobelts showed responses of 2.80 and 2.20% to C₂H₅OH concentrations of 50 and 100 ppm, respectively. In contrast, the Au-functionalized SnO₂ nanobelts showed responses of 313.25 and 194.77%, respectively, to the same C₂H₅OH concentrations. Furthermore, SnO₂ nanobelts functionalized with Au showed a higher response than those functionalized with other metal catalysts, such as Pd, Pt and Ag. Both the response and recovery times of the SnO₂ nanobelts were decreased slightly by Au-functionalization regardless of the C₂H₅OH concentration. In addition, this paper discusses the enhanced sensing properties of SnO₂ nanobelts functionalized with Au.

1. Introduction

Ethanol sensors are commonly applied in the biomedical and chemical industries to assess wine quality, food degradation, to identify drunk drivers, and to monitor fermentation and other processes in chemical industries, etc. [1]. Metal oxide one-dimensional (1D) nanostructures, including SnO₂, ZnO, In₂O₃ and TiO₂, have been studied for general-purpose gas sensor applications because 1D nanostructure sensors offer the advantages of higher sensitivity, shorter response and recovery times and lower cost than the thin film-type sensors owing to their high surface-to-volume ratios [2–6]. Among these metal oxides, SnO₂ may be the most widely used material for gas sensing due to the high mobility of conduction electrons, and good chemical and thermal stability under the operating

conditions of sensors [7,8]. This sensing performance can be enhanced further by incorporating a surface functionalization technique into their simple 1D nanostructure sensors [9]. Noble metal catalysts, such as Pd, Pt, Au, and Ag, have been used for functionalization to enhance the interaction of the target gas with the oxygen absorbed on the surface [10–13]. This paper reports the synthesis, structure and C₂H₅OH gas sensing properties of n-type SnO₂ nanobelts functionalized with Au. The results obtained in this study were compared with those obtained previously using SnO₂ nanowires functionalized with Pt [14] and Ag [15]. The origin of the enhanced sensing properties of n-type SnO₂ nanobelts by functionalization with Au is also discussed.

2. Experimental procedure

SnO₂ 1D nanostructures were synthesized on Au-coated p-type Si (1 0 0) substrates by the thermal evaporation of Sn

powders. An aluminum boat containing the Sn powders was placed in the middle of a quartz tube inserted in a horizontal tube furnace. An Au-coated Si substrate was placed above the boat with the deposition side faced downwards. Before deposition, the tube was evacuated to 0.01 Torr using a rotary pump. The furnace was heated to 900 °C and maintained at that temperature for 2 h under a total gas pressure of 1 Torr. The furnace was then cooled to room temperature. Subsequently, a thin Au film was deposited onto the surface of some of the SnO₂ nanobelt samples by direct current (DC) magnetron sputtering (substrate temperature: room temperature, power: 100 W, current: 20 mA, working pressure: 1.9×10^{-2} Torr, and process time: 180 s). The Au-coated nanobelts were annealed at 700 °C for 30 min in an Ar atmosphere. The Ar gas flow rate and process pressure were 100 standard cubic centimeters per minute (sccm) and 0.8 Torr, respectively.

The Au-coated nanobelts were then annealed at 800 °C in an Ar atmosphere for 30 min to make an Au layer into discrete nanoparticles. The collected nanobelt samples were characterized by scanning electron microscopy (SEM, Hitachi S-4200) equipped with an energy dispersive X-ray spectrometer (EDXS), transmission electron microscopy (TEM, Philips CM-200) and X-ray diffraction (XRD, Philips X'pert MRD diffractometer).

For the sensing measurement, Ni (~200 nm in thickness) and Au (~50 nm) thin films were deposited sequentially by sputtering to form electrodes using an interdigital electrode mask. Fig. 1 shows a schematic diagram of the multiple-networked SnO₂ nanobelt sensors. The electrical and gas sensing properties of the as-synthesized and Au-functionalized SnO₂ nanobelts were measured at 100 °C using a home-made gas sensing measurement system. During the measurements, the nanobelt gas sensors were placed in a sealed quartz tube with an electrical feed through. A set amount of C₂H₅OH (> 99.99%) gas was injected into the testing tube through a microsyringe to obtain C₂H₅OH concentrations of 50 and 100 ppm. At the same time, the electrical resistance of the nanobelts was

monitored. The electrical resistance of the gas sensors was determined by measuring the electric current when a potential difference of 0.5 V was applied between the Ni/Au inter-digital electrodes (IDEs). The response of the n-type SnO₂ nanobelt sensors was defined as $(R_a - R_g)/R_g$ for the reducing gas, C₂H₅OH, where R_a and R_g are the electrical resistances of the sensors in air and target gas, respectively. The response time is defined as the time required for the change in electrical resistance to reach 90% of the equilibrium value after injecting the gas. The recovery time is defined as the time needed for the sensor to return to 90% above the original resistance in air after removing the gas.

3. Results and discussion

Fig. 2(a) shows FE-SEM images of the Au-functionalized SnO₂ 1D nanostructures prepared by a three-step process consisting of the thermal evaporation of Sn powders, sputter deposition of Au and thermal annealing. Scanning electron microscopy showed that SnO₂ nanobelts with widths ranging from a few hundred nanometers to a few micrometers, thicknesses of a few hundred nanometers, and lengths ranging from a few to a few tens of micrometers had been coated with Au nanoparticles with a mean diameter of ~200 nm. Au was detected in the EDX spectrum (Fig. 2(b)). The Cu detected in the EDX spectrum was not used as a catalyst but as a conductor for TEM sample preparation.

The crystal structures of the SnO₂ nanobelts functionalized with Au was examined by XRD (Fig. 2(c)). Most of the XRD peaks in the pattern fit the primitive tetragonal SnO₂. The low-magnification TEM image revealed SnO₂ nanobelts with a uniform width of approximately 500 nm and Au particles with a mean diameter of approximately 200 nm on the surface of the SnO₂ nanobelt (Fig. 2(d)). A SnO₂ single crystal nanobelt was observed on the left-hand side, whereas nanocrystalline Au was observed on the right hand side of the high-resolution TEM (HRTEM) image taken from the interface region of SnO₂ and Au (Fig. 2(e)). The reflection spots in the corresponding selected area electron diffraction (SAED) pattern (Fig. 2(f)) were identified as (1 1 0), (2 0 0) and (0 2 0) reflections of a primitive tetragonal-structured SnO₂ with lattice constants $a = 0.4738$ nm and $c = 0.3187$ nm (JCPDS no. 41-1445), indicating that the SnO₂ nanobelt in the TEM image is a single crystal. No reflection spots from the Au nanoparticles were detected, presumably because the reflection spots were too dim to be detected. The lack of Au reflection spots in the SAED pattern (Fig. 2(f)) indicates that most of the Au nanoparticles might be amorphous, but the fringe pattern in the HRTEM image of the particle (Fig. 2(e)) revealed the Au particle to be comprised mainly of nanocrystalline face-centered cubic Au. The resolved spacings between two neighboring parallel fringes were approximately 0.33 and 0.24 nm corresponding to the (1 1 0) and (2 0 0) lattice planes of primitive tetragonal SnO₂, respectively.

Fig. 3(a) shows the dynamic sensing characteristics of the multiple-networked bare SnO₂ nanobelts and Au-functionalized SnO₂ nanobelts to a reducing gas C₂H₅OH at 100 °C. Fig. 3(b) is simply the enlarged part of Fig. 3(a) at a C₂H₅OH concentration of 100 ppm drawn to show the moments of gas input and gas stop. The resistance responded well to C₂H₅OH gas. The resistance decreased rapidly when the nanobelt sensors were exposed to C₂H₅OH gas, and the resistance recovered completely to the initial value when the C₂H₅OH gas supply was stopped and air was introduced. Table 1 lists the responses measured from Fig. 3(a)–(d). The bare SnO₂ nanobelts showed responses of 2.80 and 2.20% at C₂H₅OH concentrations of 50 and 100 ppm, respectively. In contrast, the Au-functionalized SnO₂ nanobelts showed responses of 313.25 and 194.77%, respectively, to the same C₂H₅OH concentrations. Consequently, Au functionalization

improved the responses of the nanobelts by approximately 112 and 89 times at 50 and 100 ppm C₂H₅OH, respectively (Table 1). Both the response and recovery times of SnO₂ nanobelts appeared to be decreased slightly by Au-functionalization regardless of the C₂H₅OH concentration (Table 1). Therefore, the functionalized nanobelt sensor was obviously superior to the bare SnO₂ nanobelt sensor in terms of both response and sensing speed. In addition, a comparison of the sensing properties of the Au-functionalized SnO₂ nanobelts in this study with those of Pt or Ag-functionalized SnO₂ 1D nanostructures reported previously [14–20] indicates that Au functionalization is as efficient in improving the sensing properties of SnO₂ 1D nanostructures as Pt- or Ag-functionalization (Table 2). The Au-functionalized SnO₂ nanobelts showed far higher responses than Pt-functionalized SnO₂ nanowires in sensing ethanol [14], even though the former

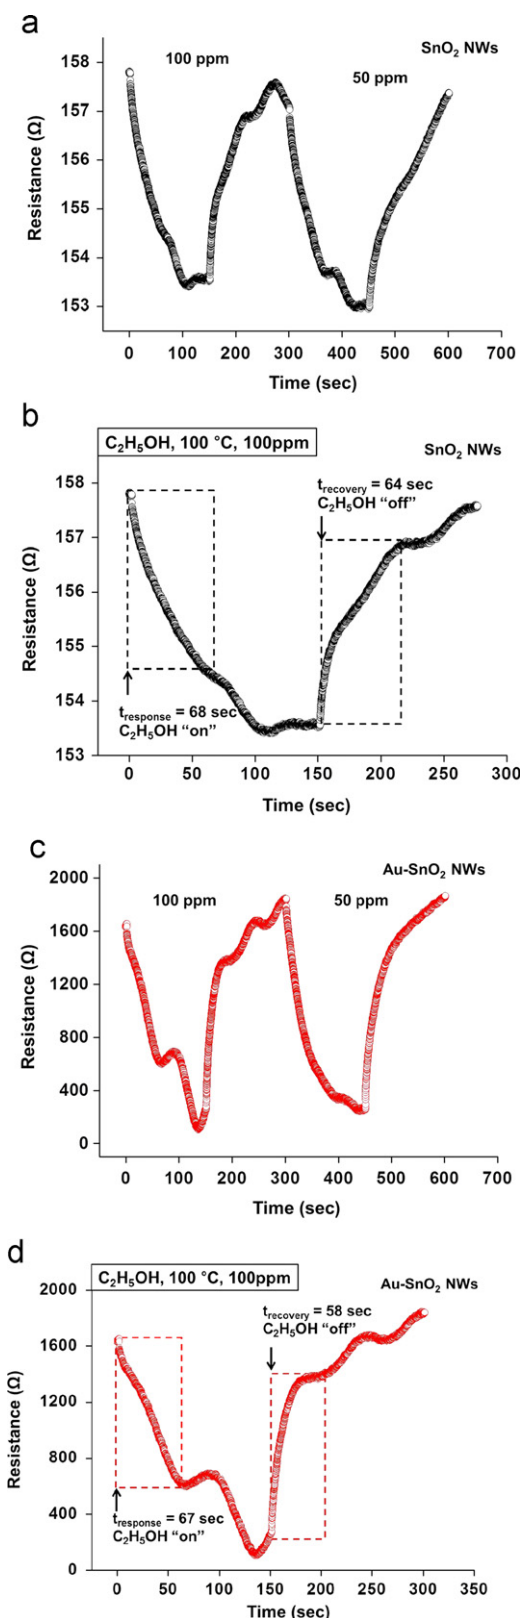

Fig. 3. Comparison of the dynamic response of an Au-functionalized SnO₂ nanobelt sensor with that of the bare SnO₂ nanobelt sensor. (a) Dynamic response of the bare SnO₂ nanobelt sensor. (b) Enlarged part of (a) at a C₂H₅OH concentration of 100 ppm drawn to reveal the moments of gas input and gas stop. (c) Dynamic response of the Au-functionalized SnO₂ nanobelt sensor. (d) Enlarged part of (c) at a C₂H₅OH concentration of 100 ppm drawn to reveal the moments of gas input and gas stop.

showed somewhat longer response and recovery times. The Au-functionalized SnO₂ nanobelts showed significantly higher responses as ethanol sensors than Ag-functionalized SnO₂ nanowires [15], even though the former showed longer recovery times.

When the SnO₂ sensing material is exposed to air, it interacts with oxygen by transferring electrons from the valence band to the adsorbed oxygen atoms, forming ionic species such as O⁻, O²⁻ and O₂⁻, as shown below [21].

The potential barrier increases with increasing the number of oxygen ions on the surface, resulting in a higher resistance [22]. When the sensors are exposed to ethanol gas, which is a reducing gas, ethanol molecules react with oxygen ions to form CO₂ and H₂O according to the following reactions, and the electrons are released back into the nanobelts [23]:

This leads to an increase in the carrier concentration of the sample and a decrease in depletion width. In other words, the depleted electrons are released back to the conduction band, which results in a sharp decrease in the resistance of the sensors. Such adsorbed oxygen and large surface-to-volume ratio increase the response of the SnO₂ nanobelt gas sensors. On the other hand, the nanobelt network probably increases the rate of oxygen adsorption and reduces the recovery time.

In the case of Au-functionalized SnO₂ nanobelts, the C₂H₅OH gas is spilt over the SnO₂ nanobelt surface by the Au nanoparticles [22], and the chemisorption and dissociation of C₂H₅OH gas [5] on the Au nanoparticle surface is enhanced owing to its high catalytic or conductive nature. Consequently, the number of electrons released from the gas species increases. In short, a combination of the spillover effect, enhancement of chemisorption and dissociation of gas, and the formation of electrons results in a higher electrical response of the Au-functionalized SnO₂ nanobelt sensor to C₂H₅OH gas.

4. Conclusions

SnO₂ nanobelts functionalized with Au were prepared using a three-step process consisting of the thermal evaporation of Sn powders, sputter-deposition of Au, and thermal annealing. Two different types of multiple-networked nanobelt sensors were fabricated using the bare and Au-functionalized SnO₂ nanobelts, respectively. The surface functionalized nanobelts with widths ranging from a few hundred nanometers to a few micrometers, thicknesses of a few hundred nanometers, and

Table 1

Responses, response times and recovery times measured at different C₂H₅OH concentrations for bare and Au-functionalized SnO₂ nanobelt sensors.

C ₂ H ₅ OH conc.	Response (%)		Response time (s)		Recovery time (s)	
	SnO ₂	Au-SnO ₂	SnO ₂	Au-SnO ₂	SnO ₂	Au-SnO ₂
100 ppm	2.20	194.77	68	67	64	58
50 ppm	2.80	313.25	82	61	62	51

Table 2

Comparison of the response, response time and recovery time of Au, Pt, Pd, and Ag-functionalized SnO₂ 1D nanostructure sensors.

Nanostructures	Gas	Conc. (ppm)	Temp. (°C)	Response (%)	Response time (sec)	Recovery time (sec)	Refs.

lengths ranging from a few to a few tens of micrometers were coated with Au nanoparticles with a mean diameter of ~200 nm. The nanobelts were primitive tetragonal-structured single crystal SnO₂. On the other hand, the Au nanoparticles were mainly amorphous but locally nanocrystalline. Au functionalization improved the responses of the SnO₂ nanobelts to C₂H₅OH by approximately 112 and 89 times at 50 and 100 ppm C₂H₅OH, respectively. Furthermore, the SnO₂ nanobelts functionalized with Au showed higher responses to C₂H₅OH than those functionalized with other metal catalysts, such as Pd, Pt, and Ag. Both the response and recovery times of the SnO₂ nanobelts were decreased by Au-functionalization regardless of the C₂H₅OH concentration. The functionalized nanobelt sensor was superior to the bare SnO₂ nanobelt sensor in terms of both response and sensing speed. The enhanced chemisorption of C₂H₅OH gas molecules and the formation of electrons by them enhances the electrical response of the Au-functionalized SnO₂ nanobelt sensor to C₂H₅OH gas.
